

III. Linear ball bearings

Linear ball bushings

Linear ball bushings

Load rating

Basic dynamic load rating

This term is arrived at based on an evaluation of a number of identical linear systems individually run in the same conditions, if 90% of them can run with the load (with a constant value in a constant direction) for a distance of 50 km without damage caused by rolling fatigue. This is the basis of the rating.

Allowable static moment

This term defines the allowable limit value of static moment load, with reference to the amount of permanent deformation similar to that used for evaluation of basic rated load (C_0).

Static safety factor

This factor is used based on the application condition as shown in Table 1.

Basic static load rating

This term defines a static load such that, at the contacting position where the maximum stress is exercised, the sum of the permanent deformation of the rolling elements and that of the rolling plane is 0,0001 time of the diameter of the rolling elements.

Static safety factors

Table 1.

Condition of use	Low limit of f_s
When the shaft has less deflection and shock	1 to 2
When elastic deformation should be considered with respect to pinch load	2 to 4
When the equipment is subject to vibration and impacts	3 to 5

Rating Life

Rating life of the linear system

As long as linear system reciprocates while being loaded, continuous stress acts on the linear system to cause flaking on the rolling bodies and planes because of material fatigue. The travelling distance of linear system until the first flaking occurs is called the life of the system. The life of the dimensions, structure, material, heat treatment and processing method, when used in the same conditions. This variation is brought about from the essential variations in the material fatigue itself. The rating life defined below is used as an index for the life expectancy of the linear system.

Rating life

Rating life is the total travelling distance that 90% of a group of systems of the same size can reach without causing any flaking when they operate under the same conditions.

The rating life can be obtained from the following equation with the basic dynamic load rating and the load on the linear system:

For ball type:

$$L = \left(\frac{C}{P} \right)^3 50,$$

where:

L - rating life, km,
 C - basic dynamic load rating N
 P - load, N.

Consideration and influence of vibration impact loads and distribution of load should be taken into account when designing a linear motion system. It is difficult to calculate the actual load. The rating life is also affected by the operating temperature. In these conditions, the expression (1) is arranged as follows:

For ball type:

$$L = \left(\frac{f_H^3 f_T f_C}{f_W P} \right) \times 50,$$

where:

- L -rating life, km,
- f_H -hardness factor (see figure 1),
- C -basic dynamic load rating, N,
- f_T -temperatuer coefficient (see figure 2),
- P -load, N,
- f_c -contact coefficient (see table 2),
- f_w -load coefficient (see table 3).

The rating life in hours can be calculated by obtaining the travelling distance per unit time. The rating life in hours can be obtained from the following expression when the stroke length and the number of strokes are constant:

$$L_h = \frac{L \times 10^3}{2 l_s \times n_1 \times 60},$$

where:

- L_h -rating life in hours, hr.,
- l_s -stroke length, m,
- L -rating life, km,
- n_1 -no of strokes per minute, cpm.

Hardness factor

The shaft be sufficiently hardened when a linear bushing is used. If not properly hardened, permissible load is lowered and the life of the bushing will be shortened

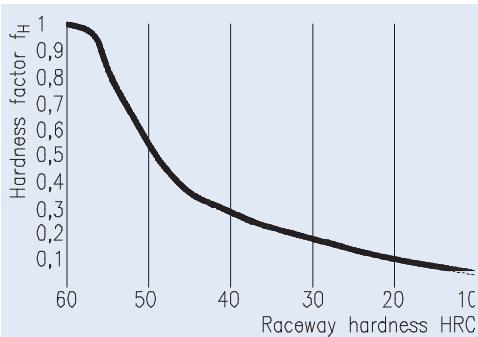

Fig. 1

Temperature coefficient

If the temperature of the linear system exceeds 100°C, Hardness of the linear system and the shaft lowers to deresure the permissible load compared to that of the linear system used at room temperature rise shortens the rating life.

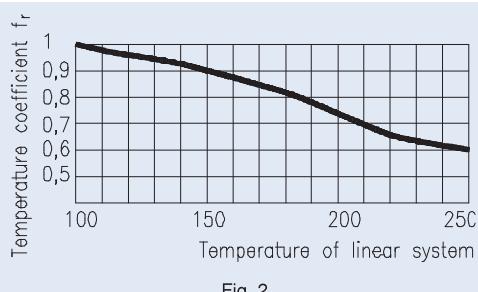

Fig. 2

Contact coefficient

Generally two or more linear bushings are used on one shaft. Thus, the load on each linear system differs depending on each precessing accuracy. Because the linear bushings are not loaded equally, the number of linear bushings per shaft changes the permissible load of system.

Contact coefficient

Table 2

Number of linear systems per shaft	Contact coefficient f_c
1	1,00
2	0,81
3	0,72
4	0,66
5	0,61

Load coefficient

When calculating the load on the linear system, it is necessary to accurately obtain object weight, inertial force based on motion speed, moment load, and each transition as time passes. However, it is difficult to calculate those values accurately because reciprocating motion involves the repetition of start and stop as well as vibration and impact. A more practical approach is to obtain the load coefficient by taking the actual operating conditions into account.

Load coefficient

Table 3

Operating Conditions	f_w
Operation at low speed(15m/min. or less) without impulsive shock from outside	1,0 to 1,5
Operation at intermediate speed (60 m/min. or less) without impulsive shock	1,5 to 2,0
Operation at high speed (over 60 m/min.) With impulsive shock from outside	2,0 to 3,5

Frictional resistance

The static frictional resistance of the MTK linear system is so low as to be only slightly different from the kinetic frictional resistance, enabling smooth linear movement from low to high speeds. In general, the friction resistance is expressed by the following equation.

$$F = \mu \cdot W + f,$$

where:

- F -frictional resistance,
- μ -coefficient of friction,
- W -load weight,
- f -sealing resistance.

The frictional resistance of each MTK linear system depends on the model, load weight, speed, and lubricant. The sealing resistance depends on lip interference and lubricant, regardless of the load weigh. The sealing resistance of one linear system is about 200 to 500 gf. The coefficient of friction depends on the load weight, moment load, and preload. Table 6 shows the coefficient of kinetic friction of each type of linear system which has been installed and lubricated properly and applied with normal load (P/C= 0,2)

Coefficient of linear system friction

Table 4

Linear System Type	Models	Coefficient of Friction
Linear Bushing	LM LME LMB	0,002 to 0,003

Ambient working temperature

The ambient working temperature range for each MTK linear system depends on the model. Consult MTK on use outside the recommended temperature range.

Temperature conversion equation:

$$C = \frac{5}{9}(F-32)$$

$$F = 32 + \frac{9}{5}C$$

Ambient working temperature

Table 5

Linear System Type	Models	Ambient Working Temperature
Linear Bushing	LM LME LMB	-20 to 80°C

Lubrication and dust prevention

Using MTK linear systems without lubrication increases the abrasion of the rolling elements, shortening the life span. The MTK linear systems, therefore require appropriate lubrication. For lubrication MTK recommends turbine oil conforming to ISO Standards G32 to G68 or lithium base soap grease no. 2. Some MTK linear systems are sealed to block dust out and seal lubricant in. If used in a harsh or corrosive environment, however, apply a protective cover to the part involving linear motion.

Structure and features

The MTK linear bushing consists of an outer cylinder, ball retainer, balls and two end rings. The ball retainer which holds the balls in the recirculating trucks in held inside the outer cylinder by end rings.

Those parts are assembled to optimize their required func-

tions.

The outer cylinder is maintained sufficient hardness by heat treatment, therefore it ensures the bushings projected travel life and satisfactory durability.

The ball retainer is made from synthetics to reduce running noise.

High precision and rigidity

The MTK linear bushing is reduced from a solid steel outer cylinder and incorporates an industrial strength resin retainer.

Ease of assembly

The standard type of MTK linear bushing can be loaded from any direction. Precision control is possible using only the shaft supporter, and the mounting surface can be machined easily.

Ease of replacement

MTK linear bushing of each type are completely interchangeable because of their standardized dimensions and strict precision control. Replacement because of wear or damage is therefore easy and accurate.

Variety of types

MTK offers a full line of linear bushing: The standard, integral single - retainer closed type, the clearance adjustable type and the open types. The user can choose from among these according to the application requirements to be met.

Linear ball bushing designation

Designation			
Group I	Group II	Group III	Group IV
Type	Nominal shaft diameter	Modification	Seal

Example:
LM 25 UU AJ

Type:
 LM -metric dimension series most widely used in Japan,
 LME -metric dimension series generally used in Europe,
 LMB -inch dimension series used mainly in USA.

Modification:
 No entry -standard type,
 AJ -adjustable type,
 OP -open type.

Seal:
 No entry -no seal,
 U -seal on one side,
 UU -seals on both sides.

f_T -temperature coefficient (see page 340),
 f_C -contact coefficient (see page 340).

The lifespan of a linear bushing in hours can be obtained by calculating the travelling distance per unit time.

The lifespan can be obtained from the following equation if the stroke length and the number of strokes are constant:

$$L_h = \left(\frac{L \times 10^3}{2 \times l_s \times n_1 \times 60} \right)^3, \quad (2)$$

where:

L_h -lifespan, hr,
 l_s -stroke length, m,
 L -rated life, km,
 n_1 -number of strokes per minute, cpm.

Tolerance

Note that precision of inscribed circle diameters and outer diameters for the clearance adjustable type (...-AJ) and the open type (...-OP) indicates the value obtained before the corresponding type is subjected to cutting process.

Load rating and life expectancy

The life of a linear bushing can be obtained from the following equation with the basic dynamic load rating and the load applied to the bush:

$$L = \left(\frac{f_H \times f_T \times f_C}{f_W \times P} \times \frac{C}{P} \right)^3 \times 50, \quad (1)$$

where:

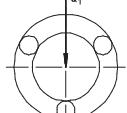

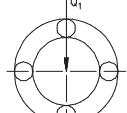

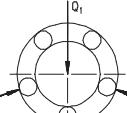

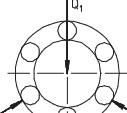

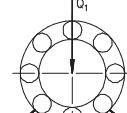

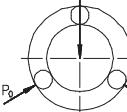

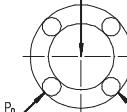

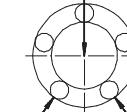

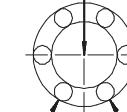

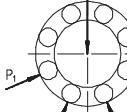

L -rated life, km,
 C -basic dynamic load rating, N,
 P -working load, N,
 f_W -load coefficient,
 f_H -hardness factor (see page 340),

Relation between ball circuits and load rating

The MTK linear bushing includes ball circuits that are spaced equally and circumferentially. The load rating varies according to the loaded position on the circumference.

The value in the dimension table indicates the load rating when the load is placed on top of one ball circuit. If the MTK linear bushing is used with two ball circuits loaded uniformly, the load rating will be greater. The following table shows the values by the number of ball circuits in such cases:

Tabel 6

Row position load ratio	Number of rows				
	3	4	5	6	8
Row position load ratio					
	$Q_1 = P_0$	$Q_1 = P_0$	$Q_1 = 1.106P_0$	$Q_1 = 1.354P_0$	$Q_1 = 1.841P_0$
Row position					
	$Q_0 = P_0$	$Q_0 = 1.414P_0$	$Q_0 = 1.618P_0$	$Q_0 = 1.732P_0$	$Q_0 = 2.052P_0$
Load ratio	$Q_0/Q_1 = 1$	$Q_0/Q_1 = 1.414$	$Q_0/Q_1 = 1.463$	$Q_0/Q_1 = 1.280$	$Q_0/Q_1 = 1.115$

Sample calculations

Obtaining the rated life and lifespan the MTK linear bushing used in the following conditions:

Linear bushing	LM20
Stroke length	50 mm
Number of strokes per minute	50 cpm
Load per bush	490 N

The basic dynamic load rating of the linear bushing is 882N from the dimension table. From equation (1) therefore, the rated life is obtained as follows:

$$L = \left(\frac{f_H \times f_T \times f_C}{f_W \times P} \times \frac{C}{P} \right)^3 \times 50 = \left(\frac{882}{490} \right)^3 \times 50 = 292 \text{ km},$$

where:

$$f_H = f_T = f_C = f_W = 1.0$$

From equation (2), the lifespan is obtained as follows:

$$L_h = \left(\frac{L \times 10^3}{2 \times e_s \times n_1 \times 60} \right) = \left(\frac{292 \times 10^3}{2 \times 0.05 \times 50 \times 60} \right) = 973 \text{ hr}$$

Selecting the linear bushing type satisfying the following conditions:

Number of linear bushing used	4
Stroke length	1 m
Traveling speed	10 m/min
Number of strokes per minute	5 cpm
Lifespan	10 hr
Total load	980 N

From equation (2), the travelling distance within the lifespan is obtained as follows

$$L = 2 \times l_s \times n_1 \times 60 \times L_h = 6000 \text{ km}$$

From equation (1), the basic dynamic load rating is obtained as follows:

$$C = \sqrt[3]{\frac{L}{50}} \times \left(\frac{f_W}{f_H \times f_T \times f_C} \right) \times P = 1492 \text{ N}$$

Assume the following with a pair of shafts each with two linear bushings:

$$f_C = 0.81, f_W = f_T = f_H = 1$$

As a result, LM30 is selected from the dimension table as the MTK linear bushing type satisfying the value of C.

Clearance and fit

When a standard-type MTK linear bushing is used with a shaft, inadequate clearance, adjustment may cause early bush failure and/or poor, rough traveling. The clearance adjustable linear bush and open linear bush can be clearance adjusted when assembled in the housing which can control the outside cylinder diameter. However, too much clearance adjustment increases the deformation of the outside cylinder, to affect its precision and life. Therefore, the appropriate clearance between the bush and shaft, and clearance

between the bush and housing are required according to the application. Table 7 shows recommended fit of the bush:

Table 7

Model	Division		Housing Loose fit	Tight fit
	Shaft Normal fit High class	Transi- tional		
LM	g6	h6	H7	J7
LMB				
LME	h6	j6	H7	J7

Note. The clearance may be zero or negative. Please attention the movement.

Shaft and housing

To optimize performance of the MTK linear bushing high precision of the shaft and housing is required.

Shaft

The rolling balls in the MTK linear bushing are in point contact with the shaft surface. Therefore, the shaft dimensions, tolerance, surface finish and hardness greatly affect the travelling performance of the bush. The shaft should be manufactured with due attention to the following points:

- Since the surface finish critically affects smooth rolling of balls, grind the shaft at 1.5 S or better.
- The best hardness of the shaft is HRC 60 to 64; Hardness less than HRC 60 decreases the life considerably, and hence reduces the permissible load. On the other hand, hardness over HRC 64 accelerates ball wear.
- The shaft diameter for the clearance adjustable linear bush and open linear bush should as much as possible be of the lower value of the inscribed circle diameter in the specification table. Do not set the shaft diameter to the upper value.
- Zero clearance or negative clearance increases the frictional resistance slightly. If the negative clearance is too tight, the deformation of the outside cylinder will become larger, to shorten the bush life.

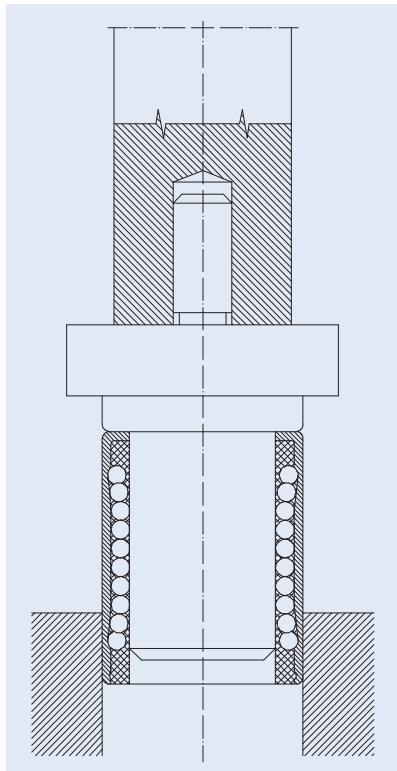

Housing

There is a wide range of housings differing in design, machining and mounting. For the fitness and shapes of housings see in table 8 and the following section on mounting.

Mounting

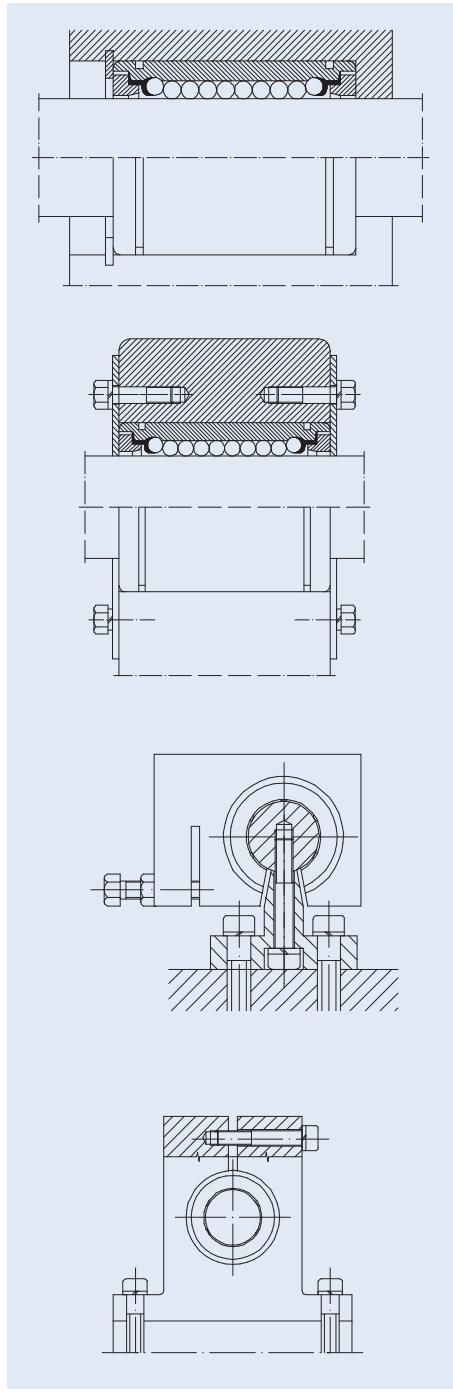

When inserting the linear bush into the bushing do not hit the linear bush on the side ring holding the retainer but apply the cylinder circumference with a proper jig and push the linear bush into the housing by hand or lightly knock it in. In inserting the shaft after mounting the bush,

be careful not to shock the balls. Note that if two shafts are used in parallel, the parallelism is the most important factor to assure the smooth linear movement. Take care in setting the shafts.

Exemples of mounting

The popular way to mount a linear bush is to operate it with an appropriate interference. It is recommended, however, to make a loose fit in principle because otherwise precision is apt to be minimized. The following examples show assembling of the inserted bush in terms of designing and mounting for reference.

IV. Pillow blocks

Pillow blocks

Pillow blocks

Feature

The spherical outside surface ball bearings of MTK are deep groove ball bearings with wide and narrow inner rings, consisting of insert bearings (SA200, SB200, UC200, UEL200, UK200, UCX00 and UC300) and various housings. The types of bearing units are defined according to the different mounting methods of the bearings to shafts : the set-screws type, the adapter type, the eccentric locking collar type.

The MTK housings are mainly casting housings. There are pressed steel plate housings as well align with ease during operation and can be conveniently mounted or dismounted.

The bearing units can operate satisfactorily under working conditions, especially for machines operating in dusty or muddy surroundings. Thus, they are widely used in agricultural, construction and transmission machineries, etc.

There are various types of sealing devices for our products, such as synthetic rubber seals, slinger with synthetic rubber seals and triple lip seals etc..

Sufficient lubricating grease has been put into the bearings during manufacturing, which can act as lubricating as well as rust proof. No more grease is needed to put in during the lubricating period when the bearings operate under normal conditions. Lubricating grease can be added from the fittings when the reburbicate bearings operate under hard conditions.

The outer ring of the bearing, has spherical outside surface which can be fitted to the concave spherical surface of the housing, and the fit between them can be clearance fit or interference fit according to different conditions. This combination provides self-alignment between the self-contained bearing and the housing, and compensates for a certain alignment errors or flexing of the shaft when the bearing is in operation. This definitely increases the bearing service life

surface ball bearings during manufacturing.

Physical chemical properties of lubricating grease
Table 1

Density 1/mm	Without operation	268
	Operated 60 times	260
Dropping point 'C		128
Mechanical impurities pc/gr	10-25 μm	within 1000
	25-75 μm	within 500
	above 75 μm	0
Base oil kinematical viscosity 40° cst		80,3

The bearings usually operate below the temperature of 120°C (the measuring temperature of the outer rings is 100°C). Grease life reduction has to be taken into account when the bearing continues to operate at a temperature above 70°C. The lowest operating temperature should not be lower than -30°C.

The permissible speed of rotations is connected with the fit between shaft and bearing. It is recommended that, under normal operating conditions, the fit between the bearing and the shaft is h7. Looser fit allowing lower speed is recommended when heavier load is applied.

Lubrication

The Spherical Outside Surface Ball Bearings of MTK generally use CG-2 rust proof lithium based lubricating grease, with physical chemical properties shown in the following table 1. Grease is filled in the spherical outside

Tolerance for bearing units

Tolerances on inner rings of bearing with cylindrical bore
Unit: 0.001 mm

Nominal bore diameter		Cylindrical bore bore diameter dm deviations		d deviations		width Bi deviations		Radial run-out
d over	incl.	high	low	high	low	high	low	max.
mm								
10	18	+18	0	+22	-4	0	-120	12
18	30	+21	0	+25	-4	0	-120	15
30	50	+25	0	+30	-5	0	-120	18
50	80	+30	0	+36	-6	0	-150	22
80	120	+35	0	+42	-7	0	-200	28
120	150	+40	0	+48	-8	0	-250	35

Note: dm is defined as the arithmetical mean of the largest and smallest diameter obtained by two-point measurements.

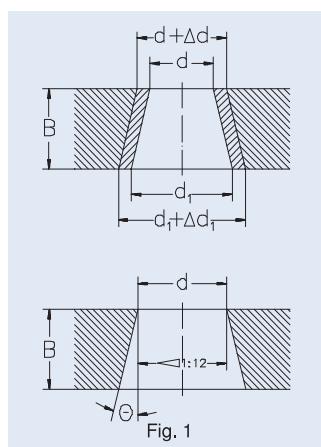

Tolerances on inner rings of bearings with tapered bore
Unit: 0.001 mm

Nominal bore diameter		Δd	$\Delta d_1 - \Delta d$	Table 3	
d over	incl.	deviations high	low	max.	min.
mm					
18	30	+33	0	+21	0
30	50	+39	0	+25	0
50	80	+46	0	+30	0
80	120	+54	0	+35	0
120	150	+63	0	+40	0

Note: The deviations from nominal taper are defined by the limits of $(\Delta d_1 - \Delta d)$, where (Δd_1) is actual deviations of d_1 from nominal diameter at the largest end of bore and Δd is actual deviation of d from bearing bore nominal diameter.
 d_1 is obtained by the following formula: $d_1 = d + 0.083333 B$, where B is width of the bearing inner ring.

The nominal taper angle = $2^\circ 23' 9.4''$.

Please refer to the figures 1.

Tolerances on outer ring

180	250	+46	0	+55	-9	+30	-16	+39	-25

Note: Dam = (Da max + Da min) / 2
 Da max - maximum measured value of Da
 Da min - minimum measured value of Da
 Dimensional tolerances for spherical inside diameter of housing are classified as H7 for clearance fit and J7 for interference fit.
 As the self - contained for bearings are equipped with locking-pin, clearance fit H7 is normally applied.

Radial internal clearance of bearings

The radial internal clearance of the bearing for the unit is the same as the value of ISO 5753, the internal radial clearance for the spherical outside surface ball bearing is usually greater than that for the same size of deep groove ball bearing. The clearance for the cylindrical bore bearing is shown in table 15 while the clearance for the tapered bore bearing is shown in table 16.

**Radial internal clearance of cylindrical bore bearings

Bearing Size selection

The bearing size is usually selected according to the required life and reliability under a specific type of load charged on the spherical outside surface ball bearing

The load applied to the bearing operating under static or slow oscillating and rotating ($n < 10\text{r/min}$) condition is defined as static load, while the load applied to the bearing operating under a speedy rotating ($n > 10\text{r/min}$) condition is defined as dynamic load.

The load capacity of the bearing is expressed by the basic dynamic load rating which is shown in the spherical outside surface ball bearing's table.

Under normal mounting, lubricating and maintaining conditions, the operating bearing will have fatigue flaking due to the repeating action of variable load charged on the contact area between the rings and rolling elements. Generally, the fatigue flaking is the cause of normal damage of rolling bearings. Therefore, the usual bearing

life refers to the bearing fatigue life. The life of group of apparently identical bearings operating under a considerable dispersion. For this reason, the bearing life is closely connected with the damaging probability or the reliability requirement.

The radial rating load of ball bearing with 90% reliability and 500 hours minimum life is shown in figure 7.

Life:

The life of a rolling bearing is defined as the total number of revolution which the bearing is capable of enduring before the first evidence of fatigue flaking develops on any one rings or rolling elements.

Reliability:

The reliability is the percentage of the bearings of a group of apparently identical bearings operating under identical conditions which can expect to attain or exceed a certain defined life. The reliability of individual bearings is the probability of the bearing to attain or exceed a defined life.

Basic rating life: For a group of apparently identical rolling bearings operating under identical

conditions, the basic rating life is defined as the total number of revolutions that 90% of the bearings can be expected to complete or exceed.

Basic rating life

The fatigue rating life of spherical outside surface ball bearings is calculated by the following formula:

$$L_{10} = \left(\frac{C}{P} \right)^3, \text{ or } \frac{C}{P} = L_{10}^{1/3}$$

where:

L_{10}	- basic rating life, 10^6 r
P	- basic dynamic load rating, N
N	- equivalent dynamic bearing load, N

The basic dynamic load rating C is a hypothetical constant load with a fixed direction under which the bearing can attain a basic life of one million revolutions theoretically. For radial bearings, the load refers to the radial load.

The equivalent dynamic bearing load P is a constant load with a fixed direction under which the bearing life is identical to that of the bearing operating under actual load.

For a bearing operating with a constant rotation speed, the basic rating life can be expressed in terms of operating hours:

$$L_{10h} = \frac{10^6}{60n} \left(\frac{C}{P} \right)^3 \text{ or } L_{10h} = \frac{10^6}{60n} L_{10} = \frac{16666}{n} \left(\frac{C}{P} \right)^3,$$

where:

L_{10h}	- basic rating life, h
n	- bearing operating speed of rotation, r/min

For easier calculation, 500 hours as base of rating life is taken, and the speed factor f_n and the life factor f_h is introduced.

$$f_n = \left(\frac{331/3}{n} \right)^{1/3}, f_h = \left(\frac{L_{10h}}{500} \right)$$

In this, the formula is simplified to:

$$C = \frac{f_h}{f_n} P,$$

The values of f_h and f_n can be found in figure 7 by referring to the operation speed n and the anticipated bearing service life L_{10h} . Then, with the radial load (or the equivalent dynamic bearing load), the basic dynamic load rating can be determined. By this way, the bearing size can be determined according to the basic dynamic load rating value in the spherical outside surface ball bearing's table. If the bearing operate under indeterminate loads and rotation speed, the following formula should be applied when calculating the bearing life:

$$P_m = \sqrt[3]{\frac{1}{N} \int_0^N P^3 dN}$$

where:

P_m	- mean equivalent dynamic bearing load, N
P	- equivalent dynamic bearing load, N

N - total revolution numbers within one load changing cycle, r

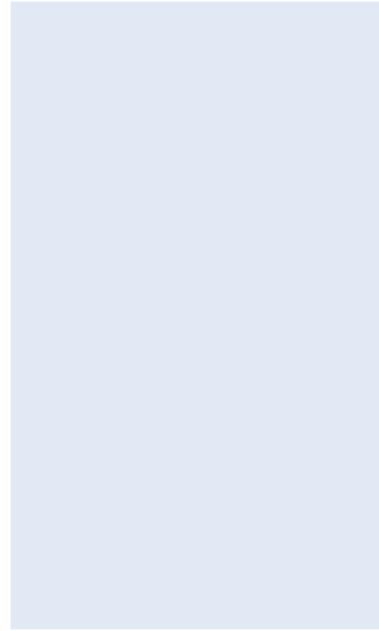

Fig. 7

Anticipated bearing service life

When selecting a bearing, one should usually predetermine an appropriate service life according to the relevant machine type, operating condition and reliability requirement. Generally the anticipated bearing service life can be determined by referring to the maintenance period of a machine.

Calculating method of equivalent dynamic bearing load P.

The basic equivalent dynamic bearing load is determined under a hypothetical condition. When calculating the bearing life, the actual load has to be converted to dynamic bearing load which is in conformity with the load condition determining the dynamic load rating. General equation for calculating the equivalent dynamic bearing load:

$$P = X F_r + Y F_a,$$

where:

P	- equivalent dynamic bearing load, N
F_r	- actual radial load, N
F_a	- actual axial load, N
X	- radial factor
Y	- thrust factor

The values of X and Y are determined by the ratio between the applied axial load F_a and the basic static load rating C_0 . The axial load which the spherical outside surface ball bearing can carry is determined by the mounting method of the bearing on the shaft.

For bearing of set-screw Locking type or eccentric Locking collar type, if flexible shafts are applied and the set-screws are tightened enough, the axial load F_a which the bearings can carry not surpass 20% of the radial load F_r .

For bearing of adapter sleeve Locking type, if the nut is properly tightened, the axial load F_a can be maximally 15% to 20% of the radial load.

The value of radial and thrust factors X and Y for spherical outside surface ball bearings can be obtained from the following Table 17.

When twist load is applied to the bearing, the equivalent dynamic bearing load is calculated by the following equation:

$$P_m = f_m P$$

where:

P_m - equivalent dynamic bearing load when considering twist load

f_m - twist load factor, which is defined as follows:
- when the twist load is small: $f_m = 1,5$
- when the twist load is big: $f_m = 2$

Example of bearing size selection

When shocking load is applied to the bearing, the equivalent dynamic bearing load can be calcuted by the following equation:

$$P_d = f_d P$$

where:

P_d - equivalent dynamic bearing load when considering shocking load

f_d - shocking load factor, which is defined as follows:
- when no shocking load or mirror shocking load is applied: $f_d = 1-1,2$
- when adequate shocking load is applied: $f_d = 1,2-1,8$

How to select the size of bearing:

one spherical outside surface ball bearings is to operate at a rotation speed of 1000r/min under only a radial load of $F_r = 3000N$, with a basic rating life of at least 20,000 hours.

Select the bearing size.

From the required rotation speed it can be found that:
 $f_n = 0,322$ (figure 7 shows about 0,32, refer to page 357).

From the required basic rating life (anticipated service life), it can be found that:

$f_h = 3,42$ (figure 7 shows about 3,4, refer to page 357).

Under only radial load, i.e.

$$P = Fr = 3000 \text{ N}$$

Therefore,

$$C = \frac{f_h}{f_n} P = \frac{3,42}{0,322} = 31,863 \text{ N}$$

A simplified way to calculate the bearing life can be applied by using figure 8.

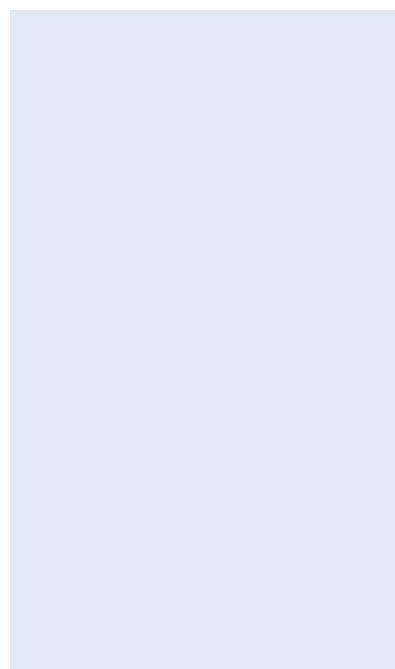

Fig. 8

Radial and thrust factors X and Y for spherical outside suface ball bearings

Table 17

Clearance for normal	e				Clearance for C3				e	
	$\frac{F_a}{C_a}$	$\frac{F_a}{F_r} \leq e$	$\frac{F_a}{F_r} > e$	e	$\frac{F_a}{F_r} \leq$	e	$\frac{F_a}{F_r} > e$	e		
	X	Y	X	Y	X	Y	X	Y	e	
0,025	1	0	0,56	2	0,22	1	0	0,46	1,74	0,3
0,04	1	0	0,56	1,8	0,24	1	0	0,46	1,61	0,33
0,07	1	0	0,56	1,6	0,27	1	0	0,46	1,46	0,36
0,13	1	0	0,56	1,4	0,31	1	0	0,46	1,3	0,41
0,25	1	0	0,56	1,2	0,37	1	0	0,46	1,14	0,47
0,5	1	0	0,56	1	0,44	1	0	0,46	1	0,54

By connecting n and the required basic rating life L_{10} with a straight line, it can be found that C/P value is 10,6. As is known, $P = F_r = 3000\text{N}$, thus the required basic dynamic load rating is:

$$C = 3000 \times 10,6 = 31,800, \text{N}$$

In this way, we can select the spherical outside surface ball bearings inside this catalogue (refer to pages 116-127).

Adjusted rating life equation

The basic rating life L_{10} calculated with bearing life calculation formula can be applied to calculate the rating life of bearings made of ordinary bearing steel (i.e. bearing life with reliability of 90%).

Due to more and more of machinery products demanding higher reliability and better quality steel (ISO 281/1-1977), an adjusted rating life calculation equation is suggested, i.e.

$$L_n = a_1 a_2 a_3 L_{10}$$

For spherical outside surface ball bearing:

$$L_n = a_1 a_2 a_3 (C/P)^3$$

where

L_n	under specified material and lubricating conditions, bearing life with $(100-n)\%$ no breaking probability (i.e. reliability).
a_1	life adjustment factor for reliability (table 18)

--	-----------

Selection of shaft

The shaft on which bearing units are mounted shall be free from band and flexure.

For the units with cylindrical bore (with set-screws or eccentric locking collar) clearance fit is usually adopted for mounting the units on the shaft, and shaft tolerances in table 21 are recommended for such loose fit, but for high speed or highly accurate operation or such application which is accompanied by heavy shock loads, interference fit is to be adopted. Table 22 shows recommended shaft tolerances for interference fit, when bearing units with eccentric locking collar are mounted on the shaft with interference fit, the eccentric locking collar may omitted.

Tapered bore bearings permit wider tolerances of the shaft since they are locked to the shaft by means of adapted sleeves.

Recommended shaft tolerances for tapered bore bearings listed in table 23.

Table 23

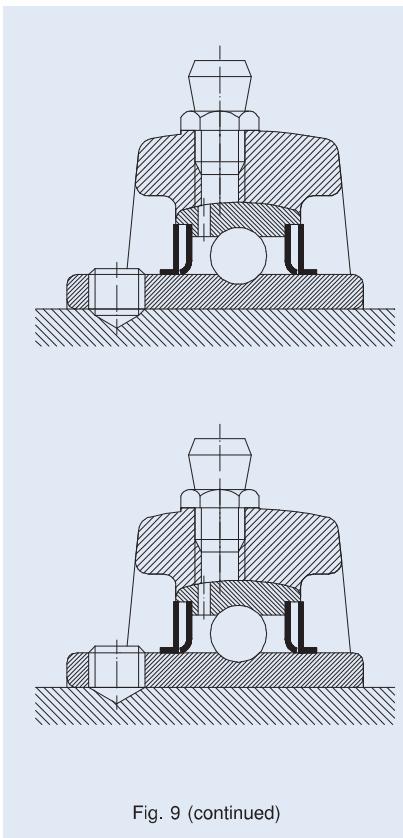

Fig. 9 (continued)

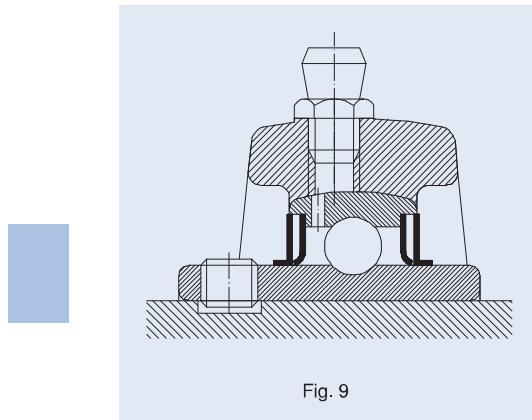

Fig. 9

Bearings units with adapter sleeve

Bearing unit with adapter sleeve permits wider shaft tolerance and can be used in applications where vibrations and shocks are heavy.

Mounting processes of these units as follows:

First, the sleeve is installed to an arbitrary position. After the shark proof washer is inserted, the nut is tightened. The proper nut tightening condition can be obtained if it

MTK

is tightened enough by hand and then rotated by 2/5 to 3/5 revolution with a spanner.

After tightening the nut, bend the shark proof washer within the slot. Otherwise, the nut may be loosened and creep may be caused between the shaft and sleeve. It is necessary the nut can not be tightened too much.

Bearings units with eccentric locking collar

The eccentric part of the collar mates with the inner ring of the bearing which is made eccentric with the collar. When locked to the shaft by hand in direction of the shaft rotation, the eccentric locking collar tightens automatically to the shaft by force of working radial load. Then, lock the set-screws provided on the collar to fix the eccentric collar to the shaft. At the shaft rotation force or load is not charged on the set-screws directly, it will not loosen during operation.

Bearings units with set-screws

There are two set-screws located at two places on one side of the wide inner ring 120° apart with which the bearing units can be mounted to the shaft. When mounting the bearing to the shaft, the torque shown in the following table 23 is recommended to tighten the set screws to shaft.

The material for cast iron housing

The material of cast iron housing under ISO/DIS GG20, the mechanical properties please refer to table 25.
